Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid (Art. 99(1) European patent convention).

**Description**

**BACKGROUND OF THE INVENTION**

5 The present invention relates to a control system suitable for making a computer program in a vehicle engine control unit match the engine, chassis and driving environment and for adaptive correction thereof in accordance with secular or environmental variations of the vehicle, or more in particular to an adaptive control system suitably capable of controlling the engine under different control conditions and under the transitions among the control conditions.

10 The sole function of conventional programs of engine control systems has been, as described in "Systems and Control", Vol. 24, No. 5, pp. 306 to 312, to supply a fuel injector and an ignition timing control unit, periodically with the results of calculations based on new observation data. In these systems, the idle engine speed control has been the only independent functional program.

These prior art control systems are based on the observation values at respective time points for  
15 control of a vehicle engine, but includes no means for evaluating the engine control conditions with the passage of time or no means for categorizing the engine conditions with running. As a result, the controllability, and hence the riding quality or drivability in the transition say, from acceleration to deceleration, is accompanied by a problem. Also, it takes a long time to make a control program developed for a predetermined engine control model match the engine in a vehicle.

20 EP-A-0 145 992 discloses a learning control system with the features set forth in the first part of claim 1. While that system classifies ranges of engine operation, the respective current condition is discriminated merely in accordance with the engine operation as a result of having been changed in response to the driver's action. Output values of the engine condition are measured, the corresponding signals are processed in accordance with the classified range of operation, and feed-back signals are produced to  
25 influence the engine operation.

Other control systems that also operate on the basis of a feed-back control are described in JP-A-57-126534 and GB-A-2 162 897. Switching between tables of control values is described as being based on a time dependent function of the different control values of the different tables.

30 **SUMMARY OF THE INVENTION**

It is an object of the present invention to provide a control system which permits comfortable driving under all control conditions of an electronically-controlled engine and is capable of improving the control in each engine control condition and, specifically, in transitions between engine control conditions for any  
35 vehicle, driving environment and/or driver.

This object is met by the adaptive control system characterized in claim 1.

In the control system of the present invention, the current engine condition is discriminated not only on the basis of signals derived from sensors detecting the actual operating condition of the engine but also from driving sensors that detect the driving operation based on the driver's intent, i.e. the intended driving  
40 operation before the actual operating condition of the engine is influenced by the driver's action. Smooth control of the transition between a current engine control condition and the next condition intended by the driver can thus be made.

**BRIEF DESCRIPTION OF THE DRAWINGS**

45 Fig. 1 is a diagram showing a configuration of an engine system using a condition discriminating-type control system according to the present invention.

Fig. 2 is a block diagram showing a detailed functional configuration of the engine control system of Fig. 1.

50 Fig. 3 is a diagram showing the relationship between the vehicle conditions and the methods of engine control corresponding to the driver's intent.

Fig. 4 is a condition transition diagram showing the transitions between engine control conditions.

Fig. 5 is a flowchart for achieving the function of a condition discriminator 4 shown in Fig. 2.

Fig. 6 is a flowchart for achieving the function of a history discriminator shown in Fig. 2.

55 Fig. 7 is a flowchart for a mixing ratio compensation factor determination section 6 in Fig. 2.

Fig. 8 is a flowchart for an air-fuel ratio control section 8, an acceleration control section 9, a deceleration control section 10, an idle speed control section 11 and an output section 12 in Fig. 2.

Fig. 9 is a flowchart for a mixing ratio adaptation coefficient updating section 14 in Fig. 2.

## DESCRIPTION OF THE PREFERRED EMBODIMENTS

The electronic engine control system according to the present invention will now be described by way of a preferred embodiment shown in the drawings.

5 The engine control conditions are classified into four types including (1) A/F control, (2) acceleration control, (3) deceleration control and (4) idle speed control. Transitions available between these four conditions are indicated by circles in the transition matrix shown in the following Table :

	<b>Arrival Departure</b>	<b>A/F control</b>	<b>Accel. control</b>	<b>Decel. control</b>	<b>Idle speed control</b>
10	<b>A/F control</b>		○	○	-
15	<b>Accel. control</b>	○		○	-
20	<b>Decel. control</b>	○	○		○
25	<b>Idle speed control</b>	-	○	-	

On the basis of the accelerator pedal angle, brake pedal angle, engine speed and vehicle speed (vehicle conditions) and on/off of the torque transmission mechanism, the computer discriminates the four control conditions of the engine and executes the control for each condition. As the result of the control, the air-fuel ratio is measured at an exhaust gas sensor and the measurement is compared with a target air-fuel ratio for each condition for evaluation (the mixing ratio of fuel to air is used instead of the air-fuel ratio in computation). If the difference between the measurement and a target air-fuel ratio is considerable, the compensation factor for the mixing ratio for each control condition is adaptively corrected and updated.

For switching the mixing ratio compensation factors between engine control conditions in transition from one to the other, a method suitable for each particular transition is taken while adaptively correcting and updating the parameters involved.

Fig. 3 shows the engine operating conditions discriminated and categorized as mentioned above. The engine operating conditions may be represented in terms of the corresponding engine control methods.

The vehicle conditions are roughly divided into a rest condition and a running condition. The driver's intents are discriminated on the basis of six different driver actions including the engaging or disengaging of the torque transmission mechanism, the depression of the brake pedal, non-depression of the brake pedal and the accelerator pedal, the depression of the accelerator pedal, the depressed accelerator pedal at rest and the restored accelerator pedal.

When the torque transmission mechanism is on (engaged) and the accelerator pedal is depressed, an engine control for the acceleration requirement is performed. With the vehicle running, when the accelerator pedal is released and the brake pedal is depressed, a deceleration control is performed. At this time, when the accelerator pedal is released and the engine speed is excessively high, a fuel cut-off control is performed. In order to discriminate between the deceleration control and the fuel cut-off control, the engine speed is detected as an additional parameter.

50 In the running condition, if the vehicle is neither accelerated nor decelerated, an air-fuel ratio control is performed to maintain the air-fuel ratio at a desired value.

Now, the depression and release of the brake pedal can be discriminated by the signal  $\theta_{br}$  from the brake pedal angle detector 35.

When the torque transmission mechanism is off, an idle speed control comes into action to control the engine speed to maintain it at a desired value. At this time, if the accelerator pedal is depressed, the switching to the previously mentioned air-fuel ratio control is effected despite the engine is racing.

The method of discriminating and classifying the conditions of the vehicle and the intents of the driver to select the proper engine control method (operating condition) is well suited to progressively deal with the

EP 0 286 103 B1

diverse requirements of the user of the vehicle and the introduction of new techniques which meet the requirements. To the design and development engineer as well as to persons who match the engine control methods with the actual vehicle (the adjustment of the parameters), this means an advantage of understanding only the engine control method corresponding to the required category. Thus a modification of the

5 computer program requires only the modification of some modules and so on. Fig. 1 systematically shows a typical example of the structure of an electronic engine control system according to the present invention. Air sucked through an air cleaner 22 is passed through an air flow meter 24 to measure the flow rate thereof, and the air flow meter 24 delivers an output signal  $G_a$  indicating the flow rate of air to a control circuit 15.

10 The air flowing through the air flow meter 24 is further passed through a throttle chamber 28, an intake manifold 36 and a suction valve 42 to the combustion chamber 44 of an engine 1. The quantity of air inhaled into the combustion chamber 44 is controlled by changing the opening of a throttle valve 30 provided in the throttle chamber 28. The opening of the throttle valve 30 is detected by detecting the valve position of the throttle valve 30 by a throttle valve position detector 34, and a signal  $\theta_{th}$  representing the  
15 valve position of the throttle valve 30 is supplied from the throttle valve position detector 34 to the control circuit 15. The position of an accelerator pedal 32 representing the amount of depression (angle) thereof is detected by an accelerator pedal position sensor 33 which in turn delivers a signal  $\theta_{ac}$  representing the depression angle of the pedal 32 to the control circuit 15.

The opening of the throttle valve 30 is controlled by the accelerator pedal 32.

20 The throttle chamber 28 is provided with a bypass 52 for idling operation of the engine and an idle adjust screw 54 for adjusting the flow of air through the bypass 52. When the throttle valve 30 is completely closed, the engine operates in the idling condition. The sucked air from the air flow meter 24 flows via the bypass 52 and is inhaled into the combustion chamber 44. Accordingly, the flow of the air sucked under the idling condition is changed by adjusting the idle adjust screw 54. The energy created in the combustion  
25 chamber 44 is determined substantially depending on the flow rate of the air inhaled through the bypass 52 so that the rotation speed of the engine under the idling condition can be adjusted to an optimal one by controlling the flow rate of air inhaled into the combustion chamber 44 by adjusting the idle adjust screw 54.

The throttle chamber 28 is also provided with another bypass 56 and an air regulator 58 including an idle speed control valve (ISCV). The air regulator 58 controls the flow rate of the air through the bypass 56  
30 in accordance with an output signal  $N_{IDL}$  of the control circuit 15, so as to control the rotation speed of the engine during the warming-up operation and to properly supply air into the combustion chamber at a sudden change in, especially sudden closing of, the valve position of the throttle valve 30. The air regulator 58 can also change the flow rate of air during the idling operation.

The fuel from the fuel tank 70 is supplied under pressure to a fuel injector 76 through a fuel line 60, and  
35 an output signal  $INJ$  of the control circuit 15 causes the fuel injector 76 constituting fuel injection control device 2 with other electronic devices which are not shown in the drawing to inject the fuel into the intake manifold 36.

The quantity of the fuel injected by the fuel injector 76 is determined by the period for which the fuel injector 76 is opened and by the difference between the pressure of the fuel supplied to the injector and the  
40 pressure in the intake manifold 36 in which the pressurized fuel is injected. It is however preferable that the quantity of the injected fuel should depend only on the period for which the injector is opened and which is determined by the signal supplied from the control circuit 10. Accordingly, the pressure of the fuel supplied by the fuel pressure regulator (not shown) to the fuel injector 76 is controlled in such a manner that the difference between the pressure of the fuel supplied to the fuel injector 76 and the pressure in the intake  
45 manifold 36 is kept always constant in any driving condition.

As described above, the fuel is injected by the fuel injector 76, the suction valve 42 is opened in synchronism with the motion of a piston 85, and a gaseous mixture of air and fuel is sucked into the combustion chamber 44.

50 The mixture is compressed and fired by the spark generated by an ignition plug 46 so that the energy created through the combustion of the mixture is converted to mechanical energy.

The exhaust gas produced as a result of the combustion of the mixture is discharged into the open air through an exhaust valve (not shown), an exhaust pipe 86, a catalytic converter 92 and a muffler 96.

A  $\lambda_A$  sensor 90 is provided in the exhaust pipe 86 to detect the fuel-air mixture ratio of the mixture sucked into the combustion chamber 44. An oxygen sensor ( $O_2$  sensor) is usually used as the  $\lambda_A$  sensor 90  
55 and detects the concentration of oxygen contained in the exhaust gas so as to generate a voltage signal corresponding to the concentration of the oxygen contained in the exhaust gas. The output signal of the  $\lambda_A$  sensor 90 is supplied to the control circuit 15.

The control circuit 15 has a negative power source terminal 98 and positive power source terminal 99

which are connected to the output circuit 12 (not shown) included in the control circuit 15.

In the event the control circuit 15 generates the signal IGN for causing the ignition plug to spark, the signal is delivered to the output circuit 12 to cause an IGN voltage to be applied to the primary winding of an ignition coil 50.

5 As a result, a high voltage is induced in the secondary winding of the ignition coil 50 and supplied through a distributor 48 to the ignition plug 46 so that the plug 46 fires to cause combustion of the mixture in the combustion chamber 44. The mechanism of firing the ignition plug 46 will be further detailed. The ignition plug 46 has a positive power source terminal 102, and the control circuit 15 also has an output circuit 12 for controlling the primary current through the primary winding of the ignition coil 50. The series  
10 circuit of the primary winding of the ignition coil 50 and the output circuit 12 is connected between the positive power source terminal 102 of the ignition coil 50 and the negative power source terminal 99 of the control circuit 15. When the output circuit is activated, electromagnetic energy is stored in the ignition coil 50, and when the output circuit 12 is cut off, the stored electromagnetic energy is released as a high voltage to the ignition plug 46. The plug 46, distributor 48 and ignition coil 50 constitute the ignition control  
15 device 3. The engine 1 is further provided with a rotational sensor 108 for detecting the angular position of the rotary shaft of the engine, and the sensor 108 generates a reference signal N in synchronism with the rotation of the engine, e.g. every 360° of the rotation.

A brake pedal angle detector 35 detects the position of a foot brake (not shown) and delivers signal  $\theta_{br}$  to the control circuit 15 when the foot brake is depressed.

20 The output circuit has been discussed in connection with the energization of the ignitor coil 50 and fuel injection by fuel injector 76. The output circuit is also utilized for outputting the  $N_{IDL}$  control signal to the air regulator 58.

25 Fig. 2 is a block diagram showing a detailed software configuration of the control system 15 making a centerpiece of a condition discriminating-type adaptive control method for engines according to an embodiment of the present invention.

30 In the configuration shown in Fig. 2, the control system comprises a condition discrimination section 4 supplied with various parameters representing driver's activity and condition of vehicle for deciding one of the engine control conditions shown in Fig. 3, a history judgement section 5 for comparing the control condition with a past control condition, a mixing ratio compensation factor determining section 6 for calculating a fuel-air mixing ratio compensation factor in accordance with the control condition decided, and a control section 13 including an air-fuel ratio control section 8, an acceleration control section 9, a deceleration control section 10 and an idle speed control section 11 selected in accordance with the result of condition discrimination.

35 Further, the control unit 15 includes an output section 12 for adjusting and outputting a signal mode of these control section outputs, from which a control signal is applied to a fuel injection control unit 2 including a fuel injector 76 and an ignition timing control unit 3 including an ignition plug 46.

40 The control unit 15 includes a mixing ratio adaptation factor updating section 14 for correcting and computing the adaptation factor of the mixing ratio in response to a detection value of a linear oxygen sensor 90 for measuring the amount of oxygen in the engine exhaust gas and a history file 7 for storing this value and applying data to the history judgement section 5 and the mixing ratio compensation factor determining section 6.

45 The condition discrimination section 4 detects the vehicle condition on the basis of the vehicle speed  $v$  produced from the vehicle speed sensor 77 and the engine speed  $N$  produced from the sensor 108, and also detects the driver's intent on the basis of the accelerator pedal angle  $\theta_{ac}$  produced from the accelerator pedal position sensor 33, the brake pedal angle  $\theta_{br}$  from the brake pedal angle detector 35 and the switching signal (on/off signal) from the torque transmission switch 75. The brake pedal angle  $\theta_{br}$  may be replaced with equal effect by a stop switch including a contact adapted to be turned on/off at a predetermined angle as a displacement point.

50 The history judgement section 5 judges whether or not the engine control condition ( $m$ ) decided at the time of the present sampling has changed from the condition ( $m^{-1}$ ) at the last sampling by making comparison with the storage in the history file 7 containing the data on the last sampling times.  $m$  indicates the number of current engine control condition and  $m^{-1}$  that of last engine control condition. The result of judgement at the history judgement section 5 is divided into two types: (1) the same control condition continued, and (2) under transition to a different control condition.

55 A transition of engine control conditions is illustrated in Fig. 4. In Fig. 4, the engine control conditions include four types of air-fuel ratio control (hereinafter referred to as  $m = 1$ ), acceleration control ( $m = 2$ ), deceleration control ( $m = 3$ ) and idle speed control ( $m = 4$ ) and the transition stages between them.

Fuel cut (FC) control is also one of the engine control conditions but is included in the deceleration

control. FC control starts from the deceleration control and returns to the deceleration control at the end thereof. The transition from FC control to acceleration control also passes through the logics of deceleration control.

The history judgement section 5 judges whether (1) the same control condition is continued, or (2) the engine is under transition from one control condition to another, and on the basis of the result of this decision, the mixing ratio compensation factor determining section 6 calculates the mixing ratio compensation factor  $K_{MR}$  corresponding to the condition (1) or (2). The result of determination at the section 6 is applied to one of the air-fuel ratio control section 8, the acceleration control section 9, the deceleration control section 10 and the idle speed control section 11. In this manner, the amount of fuel injection and the ignition timing calculated at the control unit 15 are applied to the fuel injection control unit 2 and the ignition timing control unit 3 through the output section 12.

On the other hand, whether or not the result of combustion based on the mixing ratio compensation factor  $K_{MR}$  has achieved a target mixing ratio  $K_{TR} (\ell, Ga, N)$  ( $\ell$ : Condition before transition,  $Ga$ : Amount of intake air,  $N$ : Engine speed) is determined by measuring the combustion exhaust gas with a linear oxygen sensor (wide-range air-fuel ratio sensor) 90. The air excess rate thus measured  $\lambda_A$  (Air-fuel ratio/stoichiometric air-fuel ratio) is compared with a target mixing ratio (fuel-air ratio) and the result of comparison is determined as a mixing ratio adaptation coefficient  $k(\ell)$ , which coefficient is stored in the history file 7 for utilization in the calculation of the amount of fuel injection under the same engine control condition at the next and subsequent samplings.

Now, the processing operation of the control unit 15 for each functional block thereof will be explained in detail. Fig. 5 shows a flowchart for the condition discrimination section 4. This control condition discrimination section 4 is supplied with initial data including the on/off signal of the torque transmission mechanism, the vehicle speed  $v$ , accelerator pedal angle  $\theta_{ac}$ , brake pedal angle  $\theta_{br}$ , engine speed  $N$  and the time point  $t$  when the present sampling is read in the first place at step 501. The next step 502 indicates the engine control condition ( $m$ ) one sampling time before as  $m^{-1}$  for the convenience of program processing. If step 503 decides that the torque transmission mechanism is on, step 504 decides whether or not the accelerator pedal angle  $\theta_{ac}$  is larger than "0". If the angle  $\theta_{ac}$  is larger than zero, the process proceeds to the next step 505 for calculating the accelerator pedal angular speed  $\dot{\theta}_{ac}$  from  $(\theta_{ac} - \theta_{ac}^{-1}) / (t - t^{-1})$ , where  $\theta_{ac}^{-1}$  is the accelerator pedal angle read at the immediately preceding sampling time and  $t^{-1}$  the time point of the immediately preceding sampling. The result of calculation at step 505 is compared with the maximum threshold value of accelerator pedal angle speed  $\dot{\theta}_{aca}$  at the next decision step 506, and if  $\dot{\theta}_{ac} \geq \dot{\theta}_{aca}$ , step 511 compares the engine speed  $N$  with the maximum engine  $N_a$ . If step 511 decides that  $N \leq N_a$ , it is decided that the engine control condition at the time point is acceleration ( $m = 2$ ) (step 513), and in other cases, that the air-fuel ratio control ( $m = 1$ ) is discriminated (step 512).

If step 506 decides that the relations  $\dot{\theta}_{ac} \geq \dot{\theta}_{aca}$  does not hold, step 507 compares the acceleration pedal angular speed  $\dot{\theta}_{ac}$  with the minimum threshold value of acceleration pedal angular speed  $\dot{\theta}_{acd}$ , and if  $\dot{\theta}_{ac} \leq \dot{\theta}_{acd}$ , step 514 decides that the air-fuel ratio control is discriminated ( $m = 1$ ) if the speed  $v$  is larger than zero.

If the decision at step 514 is "No", it indicates that the acceleration pedal angular speed  $\dot{\theta}_{ac}$  is not larger than the minimum threshold value of acceleration pedal angular speed  $\dot{\theta}_{acd}$  while the speed is "0", thereby representing some fault. As a result, step 515 raises an alarm and proceeds to the air-fuel control ( $m = 1$ ) (step 516) which is on safe side.

If step 507 decides that the relation  $\dot{\theta}_{ac} \leq \dot{\theta}_{acd}$  does not hold, step 508 decides whether  $v$  is larger than zero, and if the answer is "Yes", it is decided that the deceleration control ( $m = 3$ ) is discriminated. If step 508 decides the other way, it indicates that the acceleration pedal angular speed  $\dot{\theta}_{ac}$  is not larger than its threshold value  $\dot{\theta}_{acd}$  and that the speed  $v$  is "0", thereby representing a fault. The step 509, like step 515, thus raises an alarm and proceeds to the deceleration control ( $m = 3$ ).

If the decision at step 504 is that the relation  $\theta_{ac} > 0$  does not hold, step 517 decides if the speed  $v$  is larger than zero or not. If the answer at step 517 is "Yes", step 518 decides whether the brake pedal angle  $\theta_{br}$  is larger than zero. If the answer is "No", the step 519 compares the engine speed  $N$  with the minimum deceleration speed  $N_d$ . If it is decided that  $N$  is larger than  $N_d$  at step 519, the deceleration control ( $m = 3$ ) (step 521) is decided, and in the other case, the air-fuel ratio control ( $m = 1$ ) (step 520). If step 518 decides that  $\theta_{br}$  is larger than zero, by contrast, the process jumps to the step 521 to decide on the deceleration control ( $m = 3$ ).

If the decision at step 517 is that  $v$  is not larger than zero, the process proceeds to step 525 of deciding whether or not the vehicle is equipped with automatic transmission (AT), and if the decision is "YES", step 527 decides on the idle speed control ( $m = 4$ ). Whether or not the vehicle is equipped with AT is set at the time of mounting the control unit on the vehicle. If step 525 decides that the vehicle is not equipped with

AT, it indicates that the vehicle is of manual transmission type with the acceleration pedal angle  $\theta_{ac}$  open and the speed at zero, and therefore in order to prevent engine stall, an alarm is issued (step 526) and the idle speed control ( $m = 4$ ) is discriminated (step 527).

If the step 503 at the beginning of the flow chart decides that the torque transmission mechanism is off, 5 step 522 decides whether the acceleration pedal angle  $\theta_{ac}$  is larger than zero, and if the answer is "Yes", step 523 decides on the air-fuel ratio control ( $m = 1$ ). If the decision is the other way, step 524 decides on the idle speed control ( $m = 4$ ). This flow of operation achieves the function of the condition discrimination section 4.

The history judgement section 5 will be explained in detail with reference to the flowchart of Fig. 6. The 10 control condition  $m$  at the present time received from the above-mentioned condition discrimination section 4 is compared with the immediately preceding control condition  $m^{-1}$  at step 601. If they coincide with each other, step 602 reads the immediately preceding control condition  $\ell$ , the number  $i$  of detonations occurred from the start of transition (the number of samplings mentioned above), and the number  $n(\ell, m)$  of detonations for smoothing in the process of transition from the condition  $\ell$  to the condition  $m$  from the 15 history file 7. Step 603 increases the value  $i$ , followed by step 604 for deciding whether  $i \geq n(\ell, m)$ , and if the answer is "Yes", it is decided that the same condition is continued, so that the value  $i$  is restricted to the same value  $n(\ell, m)$  with the values  $m$  and  $i$  stored. If the decision at step 604 is "No", on the other hand, it is decided that the transition is undergoing, and the process jumps to step 606 thereby to store the values  $m, i$  as they are.

20 If the first step 601 decides that  $m$  is not equal to  $m^{-1}$ , "1" is set as the value of  $i$  (step 607), and the immediately preceding condition  $m^{-1}$  is applied to  $\ell$  (step 608). These values  $m, \ell, i$  are stored. The history judgement is made by the aforementioned process flow, and the result of judgement is used for the process in the next mixing ratio compensation factor determining section 6.

25 Fig. 7 shows a flow configuration of a mixing ratio compensation calculation for achieving the function of the mixing ratio compensation factor determining section 6.

In the calculation of the mixing ratio compensation factor in Fig. 7, the section 6 is supplied with air flow rate  $G_a$  from the air flowmeter 24, the present control condition  $\ell$  from the above-mentioned history judgement section 5, the next control condition  $m$ , the number  $i$  of detonations occurred since the start of transition, and the number  $n(\ell, m)$  of detonations for smoothing in the process of transition from condition 30  $\ell$  to condition  $m$  at step 701. The next step 702 decides whether the same condition is continued ( $\ell = m$ ), and if the same control condition is continued, step 703 applies the mixing ratio adaptation coefficient  $K(\ell)$  corresponding to the engine control condition  $\ell$ . Then, the mixing ratio compensation factor  $K_{MR}$  is calculated from equation (1) on the basis of the mixing ratio target coefficient  $K_{TR}(\ell, G_a, N)$  determined by the control condition  $\ell$ , air flow rate  $G_a$  and engine speed  $N$  and the mixing ratio adaptation coefficient  $K(\ell)$ .

$$K_{MR} = K(\ell) \cdot K_{TR}(\ell, G_a, N) \quad (1)$$

If step 702 decides that the control condition is under transition from  $\ell$  to  $m$ , the process proceeds to 40 step 705 for application of the mixing ratio adaptation coefficients  $K(\ell)$  and  $K(m)$  for the conditions  $\ell$  and  $m$  respectively. Step 705 calculates the weighted average of the mixing ratio target coefficient  $K_{TR}(\ell, G_a, N)$  for the control condition  $\ell$  and the mixing ratio target coefficient  $K_{TR}(m, G_a, N)$  for the control condition  $m$  in the manner shown in equation (2) thereby to determine the mixing ratio compensation factor  $K_{MR}$  under transition.

45

$$K_{MR} = \frac{n(\ell, m) - i}{n(\ell, m)} K(\ell) K_{TR}(\ell, G_a, N) + \\ \frac{i}{n(\ell, m)} K(m) K_{TR}(m, G_a, N) \dots \quad (2)$$

55 By use of the mixing ratio compensation factor  $K_{MR}$  produced by the foregoing steps, one of the air-fuel ratio, acceleration, deceleration and idle speed controls 8, 9, 10, 11 is effected as shown at steps 801 to 809 in Fig. 8, and further followed by the processing at the output section 12 shown by steps 810 to 813 in the same diagram.

EP 0 286 103 B1

Step 801 calculates the amount of fuel injection  $G_f$  from the predetermined mixing ratio compensation factor  $K_{MR}$ , stoichiometric mixing ratio  $MR$ , air mass flow rate  $G_a$  and engine speed  $N$  in the manner shown by equation (3) below.

5     $G_f = K_{MR} \cdot MR \cdot \frac{G_a}{N}$     (3)

Step 802 determines the ignition timing  $Ig$  from the equation (4) below as a function of the fuel injection amount of  $G_f$  and the engine speed  $N$  in the well-known manner.

10     $Ig = f(G_f, N)$     (4)

If step 803 decides that  $m = 1$ , A/F control is involved. While in the case that step 803 decides  $m$  is not 1, the process proceed to step 804.

If step 804 decides that  $m = 2$ , that is, the acceleration control is involved, then step 808 makes 15 knocking compensation  $Ig_N$  and surging compensation  $Ig_S$  for preventing the knocking or surging, as the case may be, with the acceleration, thereby calculates the ignition timing  $Ig$  from equation (5) below for smoothing the acceleration.

20     $Ig = Ig - Ig_N - Ig_S$     (5)

In the acceleration control, the value 1 or s is used as  $n(\ell, m)$  for the requirement of response of the engine with acceleration.

If step 805 decides that  $m = 3$ , the engine speed  $N$  is compared with the fuel cut-off start engine speed  $N_{FC}$ , and if the engine speed is excessive, that is, if  $N$  is larger than  $N_{FC}$ , step 807 cuts off the fuel 25 supply. In this control step,  $G_f$  is set to zero, and the ignition timing indicated by equation (4) is used.

If step 804 decides that  $m$  is not 3, and that  $m = 4$ , it indicates the idle speed control, so that the process proceeds to step 809 for deciding whether  $i \geq n(\ell, m)$  by comparing the number  $i$  of detonations from the start of transition start with the number  $n(\ell, m)$  of detonations for smoothing in the process of transition from condition  $\ell$  to condition  $m$ . If the decision at this step is "No", it indicates that  $i$  is smaller 30 than  $n(\ell, m)$ , in which case the transition is under way to the idle speed control. During the transition, the air-fuel ratio control is effected for producing the calculation values of  $G_f$  and  $Ig$  from equations (3) and (4). Upon completion of this transition process and if step 809 decides that the decision thereat is "Yes", step 810 effects the well-known feedback control for regulating the engine speed  $N$  to the target value  $N_{IDL}$ . This idle speed control is effected in such a manner that  $N_{IDL}$  is applied to the air regulator 58 thereby to 35 regulate the air flow rate of the bypass 56 to attain the engine speed of  $N_{IDL}$ .

Explanation will be made of the functions of the steps 811 to 813 and the output section 12. First, step 811 determines the fuel injection time  $T_i$  of the injector from the value  $G_f$ , coefficient  $k_i$  and the ineffective injection time  $T_v$  of the injector obtained in the steps 801 to 807 as shown below,

40     $T_i = k_i G_f + T_v$     (5)

and applies this value to the fuel injection unit 2 (steps 811, 812). The ignition timing  $Ig$  is converted into an electrical signal (pulse train) and applied the ignition timing unit 3 (step 813).

In accordance with the control values thus obtained, the engine 1 is controlled, and the amount of 45 oxygen in the exhaust gas is measured by the linear oxygen sensor 90 for use in the calculation at the mixing ratio adaptation coefficient updating section.

The function of the mixing ratio adaptation coefficient updating section will be explained with reference to the flowchart of Fig. 9. Step 901 decides whether the condition transition is under way ( $i < n(\ell, m) ?$ ), and if the answer is affirmative, the operation is completed without updating the mixing ratio adaptation 50 coefficient. If the decision at step 901 is that the same control condition ( $i \geq n(\ell, m)$ ) is undergoing, step 902 supplies the air excess rate  $\lambda_A$  in the exhaust gas from the linear oxygen sensor 90. Step 904 calculates the mixing ratio adaptation coefficient observation value  $K_A$  from the input  $\lambda_A$  and the mixing ratio target coefficient  $K_{TR}(\ell, G_a, N)$  used in the fuel injection calculation in the manner shown in equation (6).

$$K_A = \frac{1}{\lambda A} \cdot \frac{1}{K_{TR}(t, Ga, N)} \dots (6)$$

5

This observation value  $K_A$  is liable to contain a measurement noise or measurement error, and in order to extract reproducible data from the observation data, step 904 smooths the mixing ratio adaptation coefficient  $K(t)$  by the adaptation coefficient  $K^{-1}(t)$  for the immediately preceding sampling time and the smoothing gain  $\alpha$  ( $0 \leq \alpha \leq 1$ ) as shown in the equation (7).

$$K(t) = K^{-1}(t) + \alpha(K_A - K^{-1}(t)) \quad (7)$$

The updated value of the mixing ratio adaptation coefficient thus produced at steps 901 to 904 is stored in the history file 7 (step 905).

The operating timing and data supply and delivery at each part of the control unit 15 will be explained with reference to Fig. 2. The control unit 15 has a computer built therein, which computer has a task controller for scheduling and starting programs (tasks). The method of program control which is well known is not shown.

The task controller contained in the unit 15 energizes the condition discrimination section 4 (as seen from the flowchart of Fig. 5) immediately before the start of fuel injection at each cylinder with the rotational sensor 108 as a timing monitor. Upon completion of the process of Fig. 5, the task controller starts the history judgement section 5 (as seen in Fig. 6). The engine control condition  $m$  is delivered from the condition discrimination section 4 to the history judgement section 5. The history judgement section 5 receives the data  $m^{-1}$ ,  $t$ ,  $i$ ,  $n$  ( $t, m$ ) on the immediately preceding sample from the history file 7, and stores the result of calculation in the form of  $m$ ,  $t$ ,  $i$  in the history file 7. At the end of the processing at the history judgement section 5, the mixing ratio compensation factor determining section 6 (as seen in Fig. 7) is energized. The mixing ratio compensation factor determining section 6 receives  $t$ ,  $m$ ,  $i$ ,  $n$  ( $t, m$ ) as data from the history judgement section 5, and measuring the amount of intake air flow  $G_a$ , receives the value  $k(t)$  from the history file 7. At the end of the process at the mixing ratio compensation factor determining section 6, the control unit 13 is energized. In the process, the control unit 13 receives data  $G_a$ ,  $m$ ,  $i$ ,  $n$  ( $t, m$ ). The result of calculation at the control unit 13 that is,  $G_f$ ,  $I_g$  and  $N_{IDL}$  are delivered to the output section 12. These data are converted into physical values at the output section 12 and supplied to the fuel injection control unit 2 and the ignition timing control unit 3. The control units 2, 3 produce an output in synchronism with the engine speed. The task controller energizes the mixing ratio adaptation coefficient updating section 14 (as seen in Fig. 1) at a time point where the detonation process ends. The mixing ratio adaptation coefficient updating section 14 receives the measured data of the air excess rate  $\lambda A$  and reads the previous mixing ratio adaptation coefficient  $k^{-1}(t)$  from the history file 7 and stores the updated value  $k(t)$  thereof in the file 7.

It will thus be understood from the foregoing description that according to the present invention, the vehicle conditions and the driver's intent are detected at each time, and according to the result thereof, an engine control system to be employed is determined accurately. As a result, the present invention contributes to an improved driveability, an improved selection of an operating range which varies with vehicle types, an improved matching efficiency of a control system capable of making the most of the engine performance and an improved efficiency of software development for realizing them.

Specifically, the desired value of air-fuel ratio can be always maintained in each engine control condition and in the transition between different engine control conditions. Therefore the variation in the exhaust gas characteristics is reduced and the fuel economy is improved.

At the same time, less torque variations and vehicle vibrations with air-fuel ratio improve the driveability and riding comfort.

Also, since the proper mixing ratio target coefficient  $K_{TR}(t, Ga, N)$  can be selected for each engine control condition in accordance with the driver's preference, a vehicle with superior driveability or high economy as compared with the prior art is realized, thereby meeting different requirements of individual drivers.

At the time of matching the engine control system, the above-mentioned  $n(t, m)$  is adjusted individually for each transition thereby to improve both the driveability and riding comfort of the vehicle in the process of condition transition while at the same time reducing the work loads for matching.

In transition to the acceleration control, for example, the value of  $n(t, m)$  which is normally set within

the range from 1 to 30 is set to 1, whereby the response is improved even at the sacrifice of the driving smoothness.

### Claims

- 5     1. A control system for categorised conditions of an engine, comprising  
          operating condition sensors (77, 108, 90) for detecting the operating condition of the engine,  
          actuators (2, 3) for operating the engine,  
          condition discrimination means (4) for determining an engine control condition from the detected  
10    results of the operating condition sensors (77, 108, 90),  
          a memory (7) for storing engine control parameters,  
          judgement means (5) for judging on a control mode of the engine from the control parameters read  
from the memory (7) and the output of the condition discrimination means (4),  
          control means (13) including a plurality of control modes (8...11) corresponding to the control  
15    conditions to be determined in the condition discrimination means (4) and applying an operating signal  
to said actuators (2, 3) in each control mode in accordance with the engine control condition  
determined by the condition discrimination means (4), and  
          parameter updating means (14) for extracting a control response parameter from the output of the  
operating condition sensors (77, 108, 90), thereby calculating a parameter and storing said parameter in  
20    the memory (7),  
          characterised by  
          driving sensors, including at least one of an acceleration pedal angle sensor (33), a brake pedal  
angle sensor (35) and a torque transmission sensor (75), for detecting the driving operation based on  
the driver's action,  
25    said condition discrimination means (4) detecting the current control mode (m) discriminated on the  
basis of at least one of said driving sensors (33, 35, 75), leading to a derived current control value (K-  
(m)),  
          means detecting a transition from a previous control mode (t) to the current control mode (m) on  
30    the basis of a change of the output signals of said driving sensors (33, 35, 75), wherein the previous  
control mode (t) is related to a derived previous control value (K(t)), and  
          means (6) calculating a control output applied to said actuators (2, 3) as a time-dependent function  
of the previous and current derived control values (K(t), K(m)).
- 35    2. The system of claim 1, wherein said engine control conditions include an air-fuel ratio engine control  
condition, acceleration engine control condition, deceleration engine control condition and idle engine  
control condition.
- 40    3. The system of claim 1 or 2, wherein said judgement means (5) judges whether the current discriminated  
engine control condition is a continuation of the same previous discriminated engine control  
condition, and produces the correlated judgement signal.
- 45    4. The system of any one of claims 1 to 3, wherein said parameter determining means (6) determines a  
ratio of a number corresponding to the time required for a smooth transition and a number correspond-  
ing to the time that has elapsed since the start of the transition, when there is a transition.
- 50    5. The system of claim 4, wherein said parameter determining means (6) determines the ratio as the ratio  
of the number of combustions required for a smooth transition and the number of engine combustions  
that have occurred since the start of the transition.
- 55    6. The system of any one of claims 1 to 5, wherein the control parameter determining means (6)  
determines a fuel-air mixing ratio compensation factor.
7. The system of any one of claims 1 to 6, wherein the amount of fuel injection and the ignition timing are  
calculated and produced in each control mode of the control means (13).
- 55    8. The system of any one of claims 1 to 7, wherein one of said operating condition sensors (77, 108, 90)  
is a linear oxygen sensor (90) for measuring the amount of oxygen in the engine exhaust gas as a  
control response parameter, and said adaptive parameter updating means (14) calculates a mixing ratio

adaptation coefficient and applies it to the memory (7).

9. The system of any one of claims 1 to 8, wherein said operating condition sensors include a vehicle speed sensor (77), an engine speed sensor (108), a linear oxygen sensor (90) and an air mass flow rate sensor (24).

#### Revendications

1. Système de commande pour des conditions de travail déterminées d'un moteur, comprenant  
des capteurs (77,108,90) des conditions de fonctionnement pour détecter les conditions de fonctionnement du moteur,  
des actionneurs (2,3) pour faire fonctionner le moteur,  
des moyens (4) de discrimination de conditions pour déterminer une condition de commande du moteur à partir des résultats détectés des capteurs (77,108,90) des conditions de fonctionnement,  
une mémoire (7) pour mémoriser des paramètres de commande du moteur,  
des moyens d'évaluation (5) pour décider d'un mode de commande du moteur à partir des paramètres de commande lus à partir de la mémoire (7) et du signal de sortie des moyens (4) de discrimination de conditions,  
des moyens de commande (13) comprenant une pluralité de modes de commande (8...11) correspondant aux conditions devant être déterminées dans les moyens (4) de discrimination de conditions et appliquant un signal de fonctionnement auxdits actionneurs (2,3) dans chaque mode de commande, en fonction de la condition de commande du moteur déterminée par les moyens (4) de discrimination de conditions, et  
des moyens (14) de mise à jour de paramètres pour extraire un paramètre de réponse de commande, à partir du signal de sortie des capteurs (77,108,90) des conditions de fonctionnement, et de ce fait calculer un paramètre et mémoriser ledit paramètre dans la mémoire (7),  
caractérisé par  
des capteurs de conduite, comprenant au moins un capteur (33) de l'angle de la pédale d'accélérateur, un capteur (35) de l'angle de la pédale de frein et un capteur (75) de transmission du couple, pour détecter l'opération de conduite sur la base de l'action du conducteur,  
lesdits moyens (4) de discrimination de conditions détectant le mode courant de commande ( $m$ ) discriminé sur la base d'au moins l'un desdits capteurs de conduite (33,35,75), ce qui conduit à l'obtention d'une valeur de commande actuelle ( $K(m)$ ),  
des moyens détectant une transition depuis un mode de commande précédent (1) au mode de commande actuel ( $m$ ) sur la base d'une modification des signaux de sortie desdits capteurs de conduite (33,35,75), le mode précédent de commande (1) étant associé à une valeur de commande obtenue précédemment ( $K(1)$ ), et  
des moyens (6) calculant un signal de sortie de commande appliqué auxdits actionneurs (2,3) selon une fonction, qui dépend du temps, des valeurs de commande précédentes et présentes obtenues ( $K(1)$ ,  $K(m)$ ).
2. Système selon la revendication 1, dans lequel lesdites conditions de commande du moteur comprennent une condition de commande du rapport air-carburant du moteur, une condition de commande de l'accélération du moteur, une condition de commande de la décélération du moteur et une condition de commande du ralenti du moteur.
3. Système selon la revendication 1 ou 2, dans lequel lesdits moyens d'évaluation (5) déterminent si la condition de commande actuelle discriminée du moteur est la poursuite de la même condition de commande discriminée antérieure du moteur et produit le signal d'évaluation associé.
4. Système selon l'une quelconque des revendications 1 à 3, dans lequel lesdits moyens (6) de détermination de paramètre déterminent le rapport d'un nombre correspondant à la durée nécessaire pour obtenir une transition en douceur à un nombre correspondant à la durée qui s'est écoulée depuis le début de la transition, lorsqu'il existe une transition.
5. Système selon la revendication 4, dans lequel lesdits moyens (6) de détermination de paramètre déterminent le rapport sous la forme du rapport entre le nombre de combustions nécessaires pour une transition en douceur et le nombre de combustions du moteur qui sont apparues depuis le début de la

transition.

6. Système selon l'une quelconque des revendications 1 à 5, dans lequel les moyens (6) de détermination de paramètre de commande déterminent un facteur de compensation du rapport du mélange carburant-air.
7. Système selon l'une quelconque des revendications 1 à 6, dans lequel la quantité d'injection de carburant et la séquence d'allumage sont calculées et produites lors de chaque mode de commande des moyens de commande (13).
8. Système selon l'une quelconque des revendications 1 à 7, dans lequel l'un desdits capteurs (77,108,90) des conditions de fonctionnement est un capteur linéaire d'oxygène (90) servant à mesurer la quantité d'oxygène dans les gaz d'échappement du moteur en tant que paramètre de réponse de commande, et lesdits moyens (14) de mise à jour adaptative de paramètres calculent un coefficient d'adaptation du taux de mélange et l'appliquent à la mémoire (7).
9. Système selon l'une quelconque des revendications 1 à 8, dans lequel lesdits capteurs des conditions de fonctionnement comprennent un capteur (77) de la vitesse du véhicule, un capteur (108) de la vitesse du moteur, un capteur linéaire (90) d'oxygène et un capteur (24) de débit massique d'air.

#### Patentansprüche

1. Steuersystem für kategorisierte Zustände eines Motor, umfassend  
Betriebszustands-Meßwertgeber (77, 108, 90) zur Erfassung des Betriebszustands des Motors,  
Stellglieder (2, 3) zum Betrieb des Motors,  
eine Zustands-Unterscheidungseinrichtung (4) zur Ermittlung eines Motorsteuerzustands aus den von den Betriebszustands-Meßwertgebern (77, 108, 90) erfaßten Ergebnissen,  
einen Speicher (7) zur Speicherung von Motorsteuerparametern,  
eine Beurteilungseinrichtung (5) zur Beurteilung eines Motorsteuermodus aufgrund der aus dem Speicher (7) ausgelesenen Steuerparameter und des Ausgangssignals der Zustands-Unterscheidungseinrichtung (4),  
eine Steuereinrichtung (13) mit mehreren Steuermoden (8...11), die den in der Zustands-Unterscheidungseinrichtung (4) zu bestimmenden Steuerzuständen entsprechen und zur Zuführung eines Betätigungssignals an die Stellglieder (2, 3) in jedem Steuermodus entsprechend dem von der Zustands-Unterscheidungseinrichtung (4) bestimmten Motorsteuerzustand, und  
eine Parameter-Aktualisiereinrichtung (14) zur Gewinnung eines Steuer-Ansprechparameters aus den Ausgangssignalen der Betriebszustands-Meßwertgeber (77, 108, 90), um daraus einen Parameter zu berechnen und diesen in dem Speicher (7) zu speichern,  
gekennzeichnet durch  
Fahr-Meßwertgeber mit mindestens einem Gaspedalwinkel-Meßwertgeber (33), einem Bremspedalwinkel-Meßwertgeber (35) und einem Getriebe-Meßwertgeber (75) zur Erfassung des Fahrbetriebs aufgrund des Fahrerverhaltens,  
wobei die Zustands-Unterscheidungseinrichtung (4) den aufgrund mindestens eines der Fahr-Meßwertgeber (33, 35, 75) unterschiedenen gegenwärtigen Steuermodus (m) erfaßt, der zu einem abgeleiteten gegenwärtigen Steuerwert ( $K(m)$ ) führt,  
eine Einrichtung zur Erfassung eines Übergangs von einem vorherigen Steuermodus ( $t$ ) auf den gegenwärtigen Steuermodus (m) aufgrund einer Änderung in den Ausgangssignalen der Fahr-Meßwertgeber (33, 35, 75), wobei sich der vorherige Steuermodus ( $t$ ) auf einen abgeleiteten vorherigen Steuerwert ( $K(t)$ ) bezieht, und  
eine Einrichtung (6) zum Berechnen eines Steuerausgangssignals, das den Stellgliedern (2, 3) als zeitliche Funktion des vorherigen und des gegenwärtigen abgeleiteten Steuerwerts ( $K(t), K(m)$ ) zugeführt wird.
2. System nach Anspruch 1, wobei zu den Motorsteuerzuständen ein solcher des Luft/Kraftstoffs-Verhältnisses, ein solcher der Beschleunigung, ein solcher der Verzögerung und ein solcher des Leerlaufs gehören.
3. System nach Anspruch 1 oder 2, wobei die Beurteilungseinrichtung (5) beurteilt, ob der gegenwärtige

## EP 0 286 103 B1

unterschiedene Motorsteuerzustand eine Fortsetzung des gleichen vorherigen unterschiedenen Motorsteuerzustands ist, und das korrelierte Beurteilungssignal erzeugt.

4. System nach einem der Ansprüche 1 bis 3, wobei die Parameter-Bestimmungseinrichtung (6) ein Verhältnis bestimmt aus einer Zahl entsprechend der für einen glatten Übergang erforderlichen Zeit und einer Zahl entsprechend der seit Beginn des Übergangs verstrichenen Zeit, sofern ein Übergang stattfindet.
5. System nach Anspruch 4, wobei die Parameter-Bestimmungseinrichtung (6) das Verhältnis als Verhältnis aus der Anzahl von für einen glatten Übergang erforderlichen Verbrennungen und der Anzahl von seit dem Beginn des Übergangs aufgetretenen Verbrennungen in dem Motor bestimmt.
6. System nach einem der Ansprüche 1 bis 5, wobei die Steuerparameter-Bestimmungseinrichtung (6) einen Kompensationsfaktor für das Luft/Kraftstoff-Mischverhältnis bestimmt.
7. System nach einem der Ansprüche 1 bis 6, wobei die Kraftstoff-Einspritzmenge und der Zündzeitpunkt berechnet und in jedem Steuermodus der Steuereinrichtung (13) erzeugt werden.
8. System nach einem der Ansprüche 1 bis 7, wobei einer der Betriebszustands-Meßwertgeber (77, 108, 90) ein linearer Sauerstoff-Meßwertgeber (90) ist, der die Sauerstoffmenge im Motorabgas als Steuer-Ansprechparameter mißt, und wobei die adaptive Parameter-Aktualisereinrichtung (14) einen Mischverhältnis-Adaptierkoeffizient berechnet und in den Speicher (7) eingibt.
9. System nach einem der Ansprüche 1 bis 8, wobei zu den Betriebszustands-Meßwertgebern (77, 108, 90) ein Fahrzeuggeschwindigkeits-Meßwertgeber (77), ein Motordrehzahl-Meßwertgeber (108), ein linearer Sauerstoff-Meßwertgeber (90) und ein Meßwertgeber (24) für den Luftmengendurchsatz gehören.
